Roger -

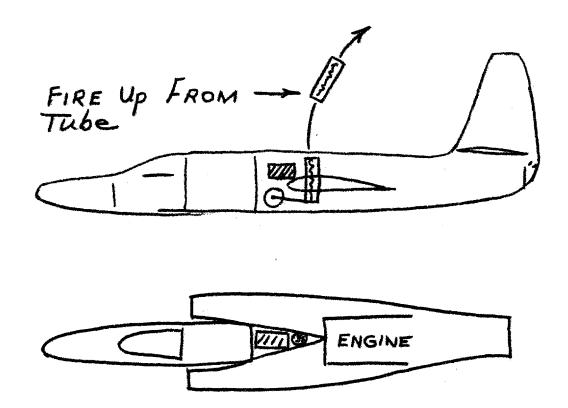

We have looked into mounting and using the Hycon crash locator beacon as a project for Sid Brewer. He had Hycon people bring their locator over to our shop for discussion.

He and I decided against wiring this unit in his birds because it evidently needs more development at this time. The percent of successful drops were practically nil. It has not operated successfully on any Air Force test at $^{\rm E}{\rm glin}$.

If the time ever comes to mount this unit on the U-2, there is a very good spot for it. One of the considerations in mounting is that it must fire up in order to always be effective in the event of a crash.

You should not have to depend on the pilot releasing this thing when he is in trouble - particularly in view of the conditions surrounding accidents involving oxygen malfunctions.

We did some engineering and came up with the following recommendation -

AS:

Approved For Release 2003/12/23: CIA-RDP62B00844R000200110064-1

- 2 -

We would mount the firing tube as shown between the engine ducts. There would be a minimum of aircraft modification and the firing loads can be easily bled out. At this position there is no C.G. effect.

The gadget can be arranged to fire manually or automatically on aircraft impact.

The present unit is much too heavy for the functions it performs. We would modify somewhat and get it down to thirty pounds. Hycon engineers agree with us.

We have not figured a cost because this unit does not seem at this time to be practicable for our application.

If a good unit of this type becomes available we have a good spot in which to mount it for maximum effectiveness.
